PMc dataset

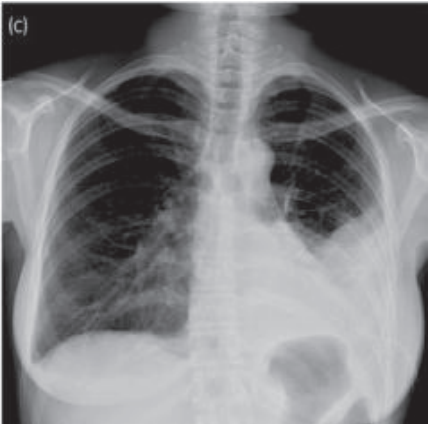

Caption

X-ray of the chest. Chest x-ray showed well-defined **huge opacity of most left hemithorax** with a shift of mediastinum to the right (Fig. 1) .

Caption

Chest X-ray performed following PCNL showing **pleural collection on the left side** On POD 9, the **left lung did not show expansion** after insertion of the drainage tube A small volume of old blood was drained without improved expansion of the left lower and middle lobes

Caption

Chest radiograph (CXR) demonstrating a **pleural effusion**. It has been estimated that a **pleural effusion** of approximately 200 mL in volume would be visible on an PA CXR (Figure 5) , whilst a smaller volume of 50 ml would be detectable on a lateral CXR [83] .

Providence

Findings

Increase in **left-sided pleural effusion**, with subsequent obscuration of the left heart border and adjacent **compressive atelectasis**. Small right-sided **pleural effusion** with adjacent atelectasis seen. There is calcification of the aortic arch. No radiographic evidence of pneumothorax. Anterior wedge compression deformities seen at at least two levels in the midthoracic spine. There is diffuse degenerative disc disease with exaggeration of the thoracic kyphosis. There is osteopenia. No acute soft tissue abnormalities.
